Metal Induced Risk of Diabetes Mellitus Due to Toxicological Effects of Mercury: Influence of Environmental Threats

SRIKANTA GURIA

Department of Zoology, Barasat Govt. College, Barasat, Kolkata-700124, West Bengal, India.

Abstract
Diabetes Mellitus (DM) is a condition of hyperglycemia due to defects of insulin secretion and/or insulin action. Toxic metals such as lead, nickel, cadmium, arsenic and mercury have been identified which accumulate in various biological samples from T2D (type 2 diabetes) patients through environmental pollution and food chain. Present study will elucidate the toxicological effects of mercury (II) chloride in the pancreatic islets and liver tissues of rat which leads to dysfunction and degeneration of pancreatic islets and liver. Photomicrograph of histology of treated pancreas exhibited the disruption of islets, disorientation of cells and disruption of connective tissue septa. In mercury (II) chloride treated group pancreatic cells were found to be pyknotic and cellular death was confirmed by membrane rupture and necrosis. Alteration of blood glucose levels were observed by glucose tolerance test. The liver sections of rats treated with mercury (II) chloride showed modification in the structure of this organ. Treated liver showed lower periodic acid/Schiff response. In this study, changes in the architecture of pancreatic islets as well as liver may be the reason behind diabetes.

Introduction
Mercury is an environmental pollutant which produces health hazard (Marx, 2002; Ratcliffe et al., 1996). Its application is found in agriculture as fungicide, in medicine as topical antiseptic, disinfectant as well as amalgam fillings in dentistry (ATSDR, 1999).

Patients with Minamata disease (methylmercury poisoning) in Japan showed incidence of diabetes mellitus (DM) (Takeuchi and Eto, 1997; Uchino et al., 1995). The study of Shigenaga (1976) showed that repeated treatment of rats with methylmercury (MeHg) induced diabetes mellitus (DM). Recently, Chen et al, (2006 and 2010) stated that mercuric...
compounds influence pancreatic β-cell dysfunction. Toxic metals due to pollution and industrialization like lead (Pb), nickel (Ni), cadmium (Cd), arsenic (As) and mercury (Hg) are associated with alteration of glucose homeostasis and cause progress of diabetes (Khan and Awan, 2014).

Toxic metal-induced oxidative stress may decrease activity of insulin gene promoter and insulin mRNA expression in pancreatic islet β-cells and, thus, alter the glucose regulations (Zheng et al., 2018). Mercury and arsenic can induce many disorders including DM by oxidative stress leading to apoptosis (Chen et al., 2009; Jomova et al., 2011).

This present study will explain the toxicological effects of mercury (II) chloride (HgCl$_2$) in the pancreatic islets as well as liver tissues of rat to explain metal-induced diabetes mellitus (DM).

**Materials and Methods**

This study will elucidate the toxicological effects of mercury (II) chloride (HgCl$_2$) in the pancreatic islets as well as liver tissues of rat by following methods.

**Animals and Housing**

The study was carried out on two groups of albino rats weighing between 100 to 120 g (total 14 rats, each group contained 7 animals). Animals in all groups were fed ad libitum and allowed free access to water and daily diet. All animals were acclimatized in laboratory condition and received human care.

Rats were divided into control group and their respective treated group (n=7/group). Rats (treated group) were injected with HgCl$_2$ (5 mg/kg/day) for 2 to 3 successive weeks (Chen et al., 2012) and control rats only received normal daily diet and water.

**Histological Investigation**

Paraffin tissue sections of liver and pancreas were stained with haematoxylin and eosin (H&E) and periodic acid/Schiff (PAS) and examined.

**Pancreatic Cells Isolation or Extraction**

Pancreas was removed using the forceps and mashed through the cell strainer into the petridish containing (0-1) M phosphate buffer saline (pH 7.2) in presence of trypsin- EDTA and tryton X 100. Cell suspension was subjected for centrifugation at 800xg for 3 minutes. Supernatant was discarded and pellet was resuspended in PBS. Cell suspension was taken for study.

**Trypan Blue Dye Exclusion Test**

Cells were treated with trypan blue dye solution for 5 minutes and observed under a light microscope and mortality index was calculated.

\[
\text{Mortality index} = \frac{\text{Number of cells with blue stained cytoplasm}}{\text{Total number of cells}} \times 100
\]

**Glucose Tolerance Test (GTT)**

Blood was collected from the tail veins of control and mercury treated rats for glucose tolerance test (GTT) by glucometer (Accu Chek Active Strip 25S) (Chakrabarti et al., 2007; Guria et al., 2012 and 2014; Guria, 2017 and 2018).

**Results and Discussion**

**Histopathological Findings of Pancreas and Analysis of Pancreatic Cells**

Histopathology of islets of Langerhan’s of pancreas of control animal revealed normal architecture with compact arrangement of cells. The islets seemed lightly stained than the surrounding acinar cells (Fig. 1A). Photomicrograph of histology of treated pancreas exhibited the disruption of islets, disorientation of cells and disruption of connective tissue septa (Fig. 1B).

Photographs of control giemsa stained pancreatic cells showed intact nuclei and membrane (Fig. 1C). In treated group pancreatic cells were found to be pyknotic and cellular death was confirmed by membrane rupture, necrosis and nuclear degeneration (Fig. 1D). Trypan blue (TB) positive response was noticed in majority of treated pancreatic cells (Fig. 1E).

**Histopathological Findings and Analysis of Liver**

Control liver tissues showed normal cytoarchitecture with visible central veins with radiating cords of hepatocytes (x100) (Fig.2A). The treated liver sections exhibited necrosis of hepatocytes, disruption of central canal, dilated sinusoidal spaces (Fig. 2B), central vein and vessel congestions (Fig. 2C) and periportal fatty infiltration (PFI) (Fig. 2D).
Fig. 1. (A) H-E stained section of control rat pancreatic islets showed normal cyto architecture (as indicated by arrows) (x400). (B) Notice the dilated interlobular connective tissue (CT) septa and degenerated islet’s cells with pyknosis in treated pancreatic islets (as indicated by arrows).

Fig. 1. (C) Giemsa stained control rat pancreatic cells showing intact nuclei and membrane (as indicated by arrows) (x400).

Fig. 1. (D) Pyknotic pancreatic cells in treated rat group showed membrane rupture, necrosis and nuclear degeneration (x400). (E) Treated rat pancreatic cells displaying trypan blue (TB) positive response (as indicated by arrows) (x400).
Fig. 2. (A) H-E stained section of normal cyto architecture rat liver with visible central veins with radiating hepatocytes (as indicated by arrows) (x 100). (B, C, D) H-E stained section of treated rat liver exhibited necrosis of hepatocytes, disruption of central canal, dilated sinusoidal spaces and central vein congestions (as indicated by arrows) (x 400).

PAS analysis of liver
Liver section of treated group showed vacuolisation in the liver parenchyma. Treated liver showed lower (periodic acid/Schiff) PAS response (Fig. 3B).

Fig. 3. (A) PAS stained section of normal rat liver (x 400). (B) PAS stained section of treated rat liver (x 400). Notice the vacuolisation in the liver parenchyma in treated group (as indicated by arrows).
Blood Glucose Level

The increased glucose level in treated rat didn’t return to control level even after 24 hr of glucose challenge (Fig. 4).

Liver and pancreas tissues both act as glucose sensor for diabetes mellitus (DM). In present study, histopathological examination of treated pancreas and liver showed the morphological alteration. Persistence of hyperglycemia was noticed in treated rat.

Chen et al., 2009 stated that islet cells were extremely sensitive to heavy metals due to high expression of metal transporters and low expression of antioxidants resulting in pancreatic islet β-cell dysfunction (Chen et al., 2009). Recent study evidenced that mercuric compounds (MeHgCl and HgCl₂) caused pancreatic islet dysfunction by apoptosis [increasing apoptotic (p53, caspase-3) related gene expressions] and ROS generation in treated mice (Chen et al., 2012).

The detrimental effects of mercury act as negative regulators of insulin signaling and resistance by producing Reactive Oxygen Species (ROS) in cells (Durak et al., 2010; Bashan et al., 2009). Previous researches have also shown that group IIb metals (cadmium, mercury and zinc) modulates glucose transport in target cells (Barnes et al., 2003). Barnes and Kircher (2005) stated that pre-treatment with HgCl₂ diminished glucose transport (Barnes and Kircher, 2005).

Guria, 2018 showed that the pancreatic sections and liver of the arsenic treated rat group exhibited marked morphological changes. Significant number of treated liver cells exhibited higher NBT (Nitroblue Tetrazolium) positive response (Guria, 2018). Alteration of glucose homeostasis was observed in arsenic treated rat (Guria, 2018). Guria et al., 2016 revealed that chromium (VI) had deleterious effect on the ultrastructure of pancreas as well as liver (Guria et al., 2016).

Conclusion

Recent study evidenced that mercuric compounds (MeHgCl and HgCl₂) caused pancreatic islet dysfunction. This observation was consistent with earlier observations on genotoxic potential of mercury (II) chloride in liver, pancreas and other tissues.

The high expression of metal transporters in islet β-cells makes the islet cells extremely sensitive to the toxic effects of heavy metals, resulting in pancreatic islet β-cell dysfunction. Pancreatic islet
β-cell degeneration and insulin resistance are the hallmark of Type2 diabetes mellitus, and thus heavy metals that reduce the function of β-cells are therefore highly relevant to T2D risk (Zheng et al., 2018; Edwards and Ackerman, 2016).

The result of present study corroborated the previous studies (Guria et al., 2016; Guria, 2018).

Therefore metal like mercury induced alteration of pancreas and liver may persuade the condition of diabetes mellitus. But further studies are needed to examine heavy metal exposures as risk factors for diabetes mellitus (DM).

Acknowledgement
Author states regards to the Head, Post Graduate Department of Zoology and Principal, Barasat Govt. College for providing infrastructure for conducting the work. The author would also like to thank Professor Madhusudan Das (Former Dean, Faculty Council for Post-Graduate Studies in Science, University of Calcutta), Department of Zoology, University of Calcutta, for his active cooperation.
