INTRODUCTION

Photovoltaic (PV) energy production is recognized as an important part of the future energy generation mix\(^1\). Because it is non-polluting, free in its availability, and is of high reliability. Therefore, these facts make the PV energy resource attractive for many applications, especially in rural and remote areas of most of the developing countries\(^2\).

India lies in the sunny belt of the world. The scope for generating power and thermal applications using solar energy is huge. Most parts of India get 300 days of sunshine a year, which makes the country a very promising place for solar energy utilization\(^3\). The daily average solar energy incident over India varies from 4 to 7 kW h/m\(^2\) with the sunshine hours ranging between 2300 and 3200 per year, depending upon location\(^4\). The technical potential of solar energy in India is huge. The country receives enough solar energy to generate more than 500,000 TW h per year of electricity, assuming 10% conversion efficiency for PV modules. It is three orders of magnitude greater than the likely electricity demand for India by the year 2015.

This paper presents a study on the design and economical analysis of a stand-alone PV system to provide the required electrical energy for a single residential household in India. The Indian location selected is Delhi.

The household pv system configuration

Fig. (1) shows the suggested block diagram of the household stand-alone PV system. Where, the function of the PV array is to convert the sunlight directly into DC electrical power and that of the battery is to store the excess power through using the battery charger. The inverter is used to convert the DC electrical power into AC power; to match the requirements of the common household AC appliances.
To predict the performance of a PV system in a site, it is necessary to collect the meteorological or environmental data for the site location under consideration. Indian Meteorological Department, Pune\(^5\) is a good source for these data. The monthly average daily solar radiation data incident on horizontal plane of the site is shown in Fig. (2). It is clear from the figure that solar energy incident in the considered site is very high especially during the summer months, where it reaches 7 kWh/m\(^2\)/day on horizontal plane.

Energy requirement in a household

The rural area household in India is simple and does not require large quantities of electrical energy used for lighting and electrical appliances. The electrical load data in a residential house are given in Table 1. The corresponding load profile for a typical day is indicated in Fig. (3).

PV System Design

To design a stand-alone PV system for the considered household, the following steps are required.

The Average Daily Solar Energy Input

Fig. (2) can be used to calculate the average daily solar energy input over the year ($G_{av}$) on a south facing surface tilted at an angle equal to the site latitude to be about 6.62 kWh/m²/day.

The Average Daily Load Demand

The average daily load demand ($EL$) can be calculated from Fig. (3), to be 5500 Wh/day.

Sizing of the PV Array

The size of the PV array, used in this study, can be calculated by the following equation [6]:

$$PV\ area = \frac{E_L}{G_{av} \times \eta_{PV} \times TCF \times \eta_{out}} \quad \ldots(1)$$

Where

- $G_{av}$ is average solar energy input per day
- $TCF$ is temperature correction factor
- $\eta_{PV}$ is PV efficiency
- $\eta_{out}$ is battery efficiency
- $\eta_{in}$ is inverter efficiency

If the cell temperature is assumed to reach 60 °C in the field, then the temperature correction factor (TCF) will be 0.8 as indicated in [7]. Assuming $= 12\%$ and $\eta_{in} = 0.85 \times 0.9 = 0.765$. Thus, using Eq. (1) the PV area is 11.3 m².

The PV peak power, at peak solar insolation (PSI) of 1000 W/m², is thus given by [7, 8]:

$$PV\ Peak\ Power = PV\ area \times PSI \times \eta_{PV} = 1356 W_{p} \quad \ldots(2)$$

The selected modules are monocrystalline silicon, with the following specifications at standard test conditions (i.e., 1000 W/m² and 25 °C)
- Peak power: 23.2 W
- Peak-power voltage: 9.6 V
- Peak-power current: 2.4167 A

Thus, 60 modules are used to supply the required energy for the residential house. The series and parallel configuration of the resulted PV array can be adjusted according to the required DC bus voltage and current, respectively. If the DC bus voltage is chosen to be 24 V, then 3 modules will be connected in series and 20 strings (each of 3 modules in series) will be connected in parallel.

Sizing of the Battery

The storage capacity of the battery can be calculated according to the following relation [8, 9]:

$$Storage\ capacity = \frac{N_c E_L}{DOD \cdot \eta_{out}} \quad \ldots(3)$$

Where

- $N_c$ is largest number of continuous cloudy days of the site
- $DOD$ is maximum permissible depth of discharge of the battery. The largest number of continuous cloudy days $N_c$ in the selected site is about 4 days. Thus, for a maximum depth of
discharge for the battery DOD of 0.8, the storage capacity becomes 35948 Wh (Eq. (3)). Since, the selected DC bus voltage is 24 V, then required ampere-hours of the battery = 35948/24 \sim 1500 Ah. If a single battery (Vision 6FM250D) of 12 V and 250 Ah is used, then 2 batteries are connected in series and 3 strings of batteries are connected in parallel to give an overall number of 6 batteries.

**Design of the Battery Charge Controller**

The battery charge controller is required to safely charge the batteries and to maintain longer lifetime for them. It has to be capable of carrying the short circuit current of the PV array. Thus, in this case, it can be chosen to handle 50 A (i.e., 2.5 A \times 20) and to maintain the DC bus voltage to about 24 V.

**Design of the Inverter**

The used inverter must be able to handle the maximum expected power of AC loads. Therefore, it can be selected as 20% higher than the rated power of the total AC loads that presented in Table 1. Thus the rated power of the inverter becomes 1020 W. The specifications of the required inverter will be 1020 W, 24 VDC, 220 VAC, and 50 Hz.

**Life cycle cost analysis**

In this section the life cycle cost (LCC) estimation of the designed stand-alone PV system is discussed. The LCC of an item consists of the total costs of owning and operating an item over its lifetime, expressed in today’s money.\textsuperscript{10-15}

The costs of a stand-alone PV system include acquisition costs, operating costs, maintenance costs, and replacement costs. All these costs have the following specifications:

- The initial cost of the system (the capital cost) is high.
- There are no fuel costs.
- Maintenance costs are low.
- Replacement costs are low (mainly for batteries).

The LCC of the PV system includes the sum of all the present worths (PWs) of the costs of the PV modules, storage batteries, battery charger, inverter, the cost of the installation, and the maintenance and operation cost (M&O) of the system. The details of the used cost data for all items are shown in Table 2.\textsuperscript{7, 12-14}

The lifetime N of all the items is considered to be 20 years, except that of the battery which is considered to be 5 years. Thus, an extra 3 groups of batteries (each of 6 batteries) have to be
purchased, after 5 years, 10 years, and 15 years, assuming an inflation rate i of 3% and a discount or interest rate d of 10%. Therefore, the PWs of all the items can be calculated as follows [10, 11]:

- PV array cost CPV = 5×60×23.2 = $6960
- Initial cost of batteries CB = 1.705 × 1500 = $2557.5
- The PW of the 1st extra group of batteries (purchased after N = 5 years) C_{B1PW} can be calculated, to be $1840.93, from

\[ C_{B1PW} = C_B \left( \frac{1+i}{1+d} \right)^N \]  

- The PW of the 2nd extra group of batteries (purchased after N = 10 years) C_{B2PW} and that of the 3rd extra group (purchased after N = 15 years) C_{B3PW} are calculated, using Eq. (4), to be $1325.14 & $953.86, respectively.
- Charger cost CC = 5.878 × 50 = $293.9
- Inverter cost C_{Inv} = 0.831 × 1020 = $847.62
- Installation cost C_{inst} = 0.1 × 6960 = $696
- The PW of the maintenance cost C_{MPW} can be calculated to be $1498.35, using the maintenance cost per year (M/yr) and the lifetime of the system (N = 20 years), from [12]:

\[ C_{MPW} = (M/yr) \times \left( \frac{1+i}{1+d} \right) \times \left[ \frac{1-\left( \frac{1+i}{1+d} \right)^N}{1-\left( \frac{1+i}{1+d} \right)} \right] \]  

Therefore, the LCC of the system can be calculated, to be $16973.3, from:

\[ ALCC = \frac{LCC}{1 - \left( \frac{1+i}{1+d} \right)^N} \]  

Once the ALCC is known, the unit electrical cost (cost of 1 kWh) can be calculated, to be $0.74/kWh, from:

\[ Unit\ electrical\ cost = \frac{ALCC}{365B_L} \]  

Therefore, in remote sites that are too far from the Indian power grid, the PV installers are encouraged to sell the electricity of their PV systems at a price not lower than $0.74/kWh to earn a profit. It is to be noted, here, that although this price is very high compared to the current unit cost of electricity in India ($0.1/kWh), this price will drop to $0.49/kWh if the future initial cost of the PV modules drops to $0.1/W. At the same time, if the future unit cost of electricity in India becomes five times its current value, due to the rapid increase in the conventional fuel prices, therefore PV energy generation will be promising in the future household electrification (in India) due to its expected future lower unit electricity cost, efficiency increase, and clean energy generation compared to the conventional utility grid.

**CONCLUSION**

Electrification of remote and rural sites worldwide is very important especially in the developing countries like India. The photovoltaic systems are considered as the most promising energy sources for these sites, due to their high reliability and safety. They represent, at the same time, a vital and economic alternative to the conventional energy generators. An electrification study for a single residential household in a remote rural site of India is carried out using a stand-alone PV system. This study presents the complete design and the life cycle cost analysis of the PV system. The results of the study indicate that electrifying a remote rural household using PV systems is beneficial and suitable for long-term investments, especially if the initial prices of the PV systems are decreased and their efficiencies are increased.
